

Implementation Notes

- Although all outputs have been depicted as per state (More), they will be moved to state transitions (Mealy) in the implementation
- This may be split into parallel software FSMs, one per controller, which may improve reliability.
- Last year, we ran the FSM at 9 Hz
- This loop may be overridden manually for testing
- Backfeed controls have been moved to hardware as of last year

Notes for Testing:

- May need to limit how fast the variable load can change to promote stability
- May need to watch for undervoltage condition, but this may be unneeded and add complexity

Nacelle Inputs & Variables

$\text{steadyRPM} = (\text{dRPM}/\text{dt} < 20 \text{ RPM/s})$
 $\text{targetRPMExceeded} = (\text{RPM} > \text{targetRPM})$
 $\text{targetRPMMet} = \text{RPM} < (\text{targetRPM} - \text{sHysteresisWindow})$
 Note: Hysteresis may not be ideal and should not be needed if PID is well tuned

Load Inputs & Variables

$\text{safetyTask} = (\text{ESTOP} \parallel \text{loadDisconnect})$
 $\text{loadDisconnect} = \text{PCCCurrent} < (0 + \text{iHysteresis})$
 $\text{producingPositivePower} = \text{PCCVoltage} > (\text{backFeedVoltage} + \text{vHysteresisWindow}/2)$
 Note: Previous versions included a fixed stage references of $> 6 \text{ V (?)}$.
